

Turbidity Curtains

Turbidity curtains are impermeable barrier, constructed of a flexible reinforced thermoplastic material. The upper hem has floatation material and the lower hem has ballast material. They are intended for construction work adjacent to a water resource to contain sediment within the work area. They allow suspended sediment at a dredging site to settle out of the water column in a controlled area, minimising the area that is affected by the increased suspended sediment usually present at a dredging site.

However, turbidity curtains are limited to project locations with less than 1-2 knot currents.
